HOMEWORK1

Deadline: 2019/10/27 23:59:59

I. INTRODUCTION

• <u>One-max Problem</u> DEFINITION (Search Space)

One-max problem is a very simple problem where is to find a specific solution make maximum value of evaluation.

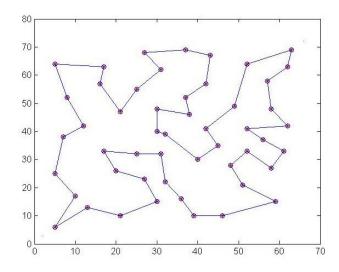

Here we give a search flow example of 10bit one-max problem:

- 10010 01101: a random example of candidate solution
- <u>11010 01101</u>: find another candidate solution (chance 1 bit of origin candidate solution)
- ..
- **.**..
- <u>11111 11111</u>: a target example of solution (optimal solution)

So, we need to find the candidate solution in the Search space, trying to pick up the better or optimal solution using some <u>heuristic technique</u>, instead of exhausted search all the candidate solution.

• <u>Traveling Salesman Problem</u> DEFINITION (Search Space)

TSP is a problem in combinatorial optimization, we given a set of coordinates of cities, you need to find the shortest possible route that visit every city exactly once and returns to the starting point.

[1] ref: https://www.researchgate.net/figure/The-Best-Solution-Achieved-by-ABCSA-for-Eil51_fig2_271132498

Figure above is a best solution of <u>eil51 dataset of TSP</u>, and here we give a search flow example of 10 cities of TSP:

- <u>1 10 9 5 6 4 2 3 78 1</u>: a random example of candidate solution
- <u>11095642387</u>1: find another candidate solution (exchange two cities or using other operator)
- **■** ...
- <u>123456789101</u>: a target example of solution (optimal solution that make minimum value of route distance)

Remarks: Each number represent the city

<u>Hill Climbing</u> DEFINITION (Search Algorithm)

Hill Climbing is a simple also essential part of metaheuristic algorithm. The spirit of the algorithm is that you just iteratively test new candidate solutions in the region of your current candidate, and adopt the new ones if they're better, this enable you to climb up the hill until you reach a local optimum.

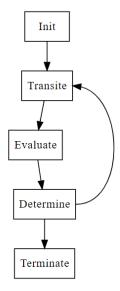

Here are several main operators of HC, also main spirit of meta-heuristic algorithm.

- 1. Initialization: give a random candidate solution of problem (one-max or TSP).
- 2. Transit: do some operation on origin candidate solution such as <u>bit-flip, bit-random-assign, two-bit-exchange, ...etc.</u> you also can develop your own operator on *Transit stage*.

Remark: normally we adopt bit-flip, bit-random-assign on one-max problem, and two-bit-exchange on TSP.

- 3. Evaluate: assessment of candidate solution, this operation will return the value of the specific candidate solution where will be used in the next stage.
- 4. Determine: return the better between origin and new candidate solution which produced by transit stage.

■ Flow Chart

Remarks: we do the loop until reach ideal solution or run out of iteration.

■ Pseudocode

```
//INITILIZATION

origin = random a candidate solution

repeat

// TRANSIT

tmp = transit(origin)

// EVALUATION and DETERMINE

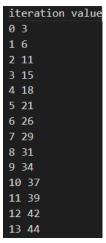

if evaluate(tmp) > evaluate(origin)

origin = tmp

until origin reach ideal solution or run out of iteration
```

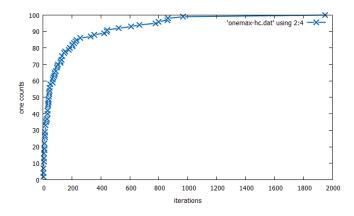

II. Homework Requirement

- There are *three* option of homework:
 - Using Hill Climbing to solve one-max problem (max score:10)
 - Using Hill Climbing to solve TSP (max score:12)
 - 1. Programing language:
 - I. C++
 - II. Java (IDE using eclipse)
 - III. Python
 - 2. You need to output the result of evaluation value w.r.t. iterations.

[2] result of 100bit one-max problem using HC

3. (OPTIONAL) Plot the figure of relation between evaluation value and iterations.

[3] figure of 100bit one-max problem using HC

4. You need to Comment out in your code.

 Do research on Hill Climbing and report it (500 words) – (score range:6-10)

You need to analyze the <u>Pros and Cons</u> of <u>Hill Climbing search algorithm</u> and <u>propose your own method</u> to improve this algorithm. You can also read the paper about HC and report it.

III. Common Requirement

- Pack your code or report as a compressed file <u>per group</u> and name as "hw1_Group#" like (hw1_Group1), upload it by team leader when finished.
- 2. Contact TA while you encounter any problem
